This week, the ability to view reports on the client side has been completely implemented. Instead of a button, the page will generate a infinite scrolling list of interactable buttons that have the title of their corresponding report. If a user clicks on a title, it will expand into a popup card with detailed information on the report. Including the name/account handle of the user(in progress), title, description, time of posting, location, and current number of votes(in progress). While the current state of the application is functional and gonig according to the initial project specifications, it is barebones in the user interface due to a lack of designs/css styling. While I work on completing upvote behavior and look into a post deletion system, I will wait for my grup members to create stylings for the app and an email/authentication system so I can link all of these aspects together. Another thing I want to do is give every user a 1 hour cooldown(im not sure about this) for posting a new report. I also feel that because of this, I may need to implement a discussion/chat section under each post and the ability to edit a post to still allow the app to keep its intended purpose of providing live information to students regarding accessibility on campus.
